

Router

Goal

Extract routes to an external file

Background

If we keep piling up more and more endpoints in one file, we'll end up with a very long and complex file. To keep things more organized, we can export a collection of routes out to another file and use them in the main app.

To do this we must first create a new file. We'll call it `routes.js` in this case, and create a new Express Router object:

```
// In routes.js
const express = require('express');
const router = express.Router();
```

Now we can set up the routes just like we did before with our `app` object:

```
router.get("/", (req, res) => {
  res.send("Hi!")
})

router.get(...)
```

Then we need to **export** the router object so it can be **imported** from our main `index.js` file:

```
module.exports = router
```

Now in our `index.js` we can **require** the router and attach it to our app:

```
const express = require('express')
const routes = require('./routes')

const app = express();

// Set up routes
app.use(routes)

...
```

Notice that in order to require our "routes" module we import it from the current director using the relative path `./routes` (without the `.js` extension).

We can actually export any code that we want out to another file using the same method! We'll see some examples in the future.

Description

Export the routes that you created in the previous exercise to a `routes.js` file and import them in your main `index.js` script.

To Submit

A zip file containing your code.
