

Knock Knock

// Login

Goal

Implement a login mechanism with hardcoded credentials

Background

Some actions in a website should only be performed by authorized users (like viewing private user data, adding comments as that user, etc.)

But, for the server to trust us, we must prove to it that we are indeed who we say we are.

There are many ways of performing **authentication**, but the most popular is asking the user to log-in with a password.

Very simply put, passwords are like keys that allow us to open digital doors behind which information is hidden. The password is a secret known only to the real person associated with the user.

If someone proves that they know the secret, you can be confident that they are the person associated with the user, and thus let them access private information and perform actions as the user.

In the next couple of exercises we'll progress through the stages of creating a secure password authentication mechanism for our websites.

Description

We'll start by using a hard-coded map of usernames and passwords to authenticate our users.

Steps

1. Download the template `knock_knock_template.zip`.

2. In the `data.js` file, define a global map of usernames and passwords
3. In the `login.js` file, implement a **server-side** check that validates the user and password combination
 1. If the login is valid, send the message "Logged in successfully!"
 2. Otherwise, send the message "Invalid username or password given!"

To Submit

A zip file containing your code.
